Routine cine supports bounded regional strain claims;
whether a focal deficit is recovered must be tested attribute by attribute

Observed

Routine cine CMR

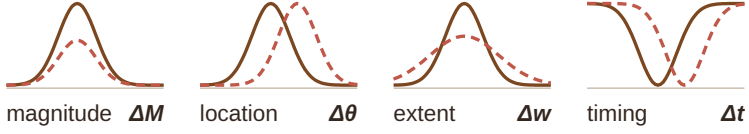

boundaries · weak texture · time

no material label

Inferred

Attributes of a focal deficit, each with its own error

tested per attribute, per estimator, per acquisition

Validated against

- **Known motion** — phantom, simulation
- **Paired DENSE / tagging** — same session
- **Tissue & outcome** — LGE, events

Selected evidence; task-specific conclusions

- Whole-slice, global and segmental Ecc agreement under matched definitions

Still requires direct assessment:

focal magnitude, location, extent and timing in the intended population and acquisition

Conceptual synthesis; no field-wide prevalence claim. Glyphs schematic.
